Package: ptw (via r-universe)

October 8, 2024

Type Package

Title Parametric Time Warping

Version 1.9-16
Description Parametric Time Warping aligns patterns, i.e. it aims to put corresponding features at the same locations. The algorithm searches for an optimal polynomial describing the warping. It is possible to align one sample to a reference, several samples to the same reference, or several samples to several references. One can choose between calculating individual warpings, or one global warping for a set of samples and one reference. Two optimization criteria are implemented: RMS (Root Mean Square error) and WCC (Weighted Cross Correlation). Both warping of peak profiles and of peak lists are supported. A vignette for the latter is contained in the inst/doc directory of the source package - the vignette source can be found on the package github site.

Parametric Time Warping

Description

Index

Parametric Time Warping aligns patterns, i.e. it aims to put corresponding features at the same locations. The algorithm searches for an optimal polynomial describing the warping. It is possible to align one sample to a reference, several samples to the same reference, or several samples to several references. One can choose between calculating individual warpings, or one global warping for a set of samples and one reference. Two optimization criteria are implemented: RMS (Root Mean Square error) and WCC (Weighted Cross Correlation). Both warping of peak profiles and of peak lists are supported. A vignette for the latter is contained in the inst/doc directory of the source package - the vignette source can be found on the package github site.

asysm

Trend estimation with asymmetric least squares

Description

Estimates a trend based on asymmetric least squares. In this case used to estimate the baseline of a given spectrum.

Usage

```
asysm(y, lambda = 1e+07, p = 0.001, eps = 1e-8, maxit = 25)
```

Arguments

y data: either a vector or a data matrix containing spectra as rows

lambda smoothing parameter (generally 1e5 - 1e8)

p asymmetry parameter

eps numerical precision for convergence

maxit max number of iterations. If no convergence is reached, a warning is issued.

Details

Asymmetric least squares (not to be confused with alternating least squares) assigns different weights to the data points that are above and below an iteratively estimated trendline, respectively. In this case, the asymmetry parameter $p (0 \le p \le 1)$ is the weight for points above the trendline, whereas 1-p is the weight for points below it. Naturally, p should be small for estimating baselines. The parameter lambda controls the amount of smoothing: the larger it is, the smoother the trendline will be.

Value

An estimated baseline

Author(s)

Paul Eilers, Jan Gerretzen

4 baseline.corr

References

Examples

```
data(gaschrom)
plot(gaschrom[1,], type = "1", ylim = c(0, 100))
lines(asysm(gaschrom[1,]), col = 2)
```

baseline.corr

Baseline Correction using asymmetric least squares

Description

This function estimates a baseline using asymmetric least squares and subtracts it from the data.

Usage

```
baseline.corr(y, ...)
```

Arguments

y signal(s) to correct. This can be a vector (containing one signal) or a matrix of signals(one signal per row)

... other arguments to the asysm function.

Value

ycorr baseline corrected signal(s): a vector or a matrix of the same dimension as the input signal(s)

Author(s)

Paul Eilers, Jan Gerretzen

References

Eilers, P.H.C. (2004) "Parametric Time Warping", Analytical Chemistry, 76 (2), 404 – 411.

```
data(gaschrom)
plot(gaschrom[1,], type = "1", ylim = c(0, 100))
lines(baseline.corr(gaschrom[1,]), col = 2)
```

bestref 5

	bestref	Identification of optimal reference
--	---------	-------------------------------------

Description

This function calculates a similarity matrix and returns the sample number that is most similar to all other samples. This is possibly preferable as a reference sample since warping then may be kept to a minimum. Either RMS or WCC may be used as similarity functions.

Usage

Arguments

x data matrix or array of signals, specified row-wise. In case of an array, the third

dimension should differentiate between the different samples

optim.crit either "WCC" or "RMS"

trwdth the width of the triangle in the WCC criterion, given as a number of data points.

Default: 20

wghts Optional weights vector in the WCC criterion; will be calculated from the trian-

gle width if necessary. Sometimes it is more efficient to pre-calculate it and give

it as an argument

smooth.param smoothing parameter for smoothing the signal when optim.crit equals "RMS".

If no smoothing is required, set this to 0

Value

A list containing two elements:

best.ref the index of the best reference(s)

crit.values the qualities as measured by either RMS or WCC

Author(s)

Jan Gerretzen, Ron Wehrens

```
data(gaschrom)
bestref(gaschrom, optim.crit = "WCC", trwdth = 50)
bestref(gaschrom, optim.crit = "RMS")
bestref(gaschrom, optim.crit = "RMS", smooth.param = 1e5)
```

6 calc.multicoef

calc.multicoef	Calculation of warping coefficients when applying more than one warping function successively

Description

Applying two (or more) warping function after each other can be described with one warping function of a higher warping degree. This function provides the coefficients of this higher degree warping function.

Usage

```
calc.multicoef(coef1, coef2)
```

Arguments

coef1	vector containing the warping coefficients of the first applied warping function
coef2	vector containing the warping coefficients of the second applied warping func-
	tion

Details

This function uses Pascal's simplex to calculate the new warping coefficients.

When applying three warping functions successively (first a, then b and finally c - here a, b and c are vectors of warping coefficients), first calculate the new coefficients for b and c, and afterwards the coefficients for a with these new coefficients. So the coefficients for the total warping function can be calculated via calc.multicoef(a, calc.multicoef(b, c)).

Value

a vector containing the corrected warping coefficients

Author(s)

Jan Gerretzen

calc.zerocoef

calc.zerocoef 7

Examples

```
data(gaschrom)
ref <- gaschrom[1,]
samp <- gaschrom[16,]
coef1 <- c(100,1.1, 1e-5)
coef2 <- c(25, 0.95, 3.2e-5)
gaschrom.ptw <- ptw(ref, samp, init.coef = coef1, try = TRUE)
ref.w <- gaschrom.ptw$reference
samp.w <- gaschrom.ptw$warped.sample
samp.w[is.na(samp.w)] <- 0
gaschrom.ptw2 <- ptw(ref.w, samp.w, init.coef = coef2, try = TRUE)
plot(c(gaschrom.ptw2$warped.sample), type = "1")

corr.coef <- calc.multicoef(coef1, coef2)
gaschrom.ptw3 <- ptw(ref, samp, init.coef = corr.coef, try = TRUE)
lines(c(gaschrom.ptw3$warped.sample), col = 2, lty = 2)</pre>
```

calc.zerocoef

Correction for warping coefficients when using zeropadding

Description

This function calculates the warping coefficients for the original range of the data, based on the warping of zero-filled data. Only needed when zeros are added in the beginning of the signal.

Usage

```
calc.zerocoef(coef, zeros)
```

Arguments

coef vector of warping coefficients of a PTW-calculation on a set of signals with

zeros added to the beginning of the signal

zeros the number of zeros added

Value

a vector containing the corrected warping coefficients

Author(s)

Jan Gerretzen

References

Bloemberg, T.G., et al. (2010) "Improved parametric time warping for Proteomics", Chemometrics and Intelligent Laboratory Systems, **104** (1), 65 – 74.

8 coda

```
padzeros calc.multicoef
```

Examples

```
data(gaschrom)
gaschrom.zf <- padzeros(gaschrom, 250)
ref <- gaschrom[1,]
samp <- gaschrom[16,]
ref.zf <- gaschrom.zf[1,]
samp.zf <- gaschrom.zf[16,]
gaschrom.ptw <- ptw(ref.zf, samp.zf)
layout(matrix(1:2,2,1, byrow=TRUE))
plot(gaschrom.ptw)
corr.coef <- calc.zerocoef(gaschrom.ptw$warp.coef, 250)
gaschrom.ptw2 <- ptw(ref, samp, init.coef = corr.coef, try = TRUE)
plot(gaschrom.ptw2)</pre>
```

coda

Chromatogram selection using the CODA algorithm

Description

The CODA algorithm calculates a so-called MCQ (Mass Chromatogram Quality) value for every row of the input. High MCQ values correspond with those chromatograms not containing spikes and/or a baseline.

Usage

```
coda(x, window = 5, smoothing = c("median", "mean"))
```

Arguments

x data matrix containing chromatograms in the rows

window width of the smoothing window

smoothing type of smoothing: whether to use running means or running medians

Details

The MCQ value of a spectrum is the inner product between the standardized, smoothed chromatogram, and the length-scaled chromatogram. In literature, a cut-off of 0.85 has been reported to work well in selecting useful chromatograms, although this is strongly data-set dependent.

difsm 9

Examples

```
data(gaschrom)
coda(gaschrom)
```

difsm

Smoothing with a finite difference penalty

Description

This function smoothes signals with a finite difference penalty of order 2.

Usage

```
difsm(y, lambda)
```

Arguments

y signal to be smoothed: a vector

lambda smoothing parameter: larger values lead to smoothing

Value

```
smoothed signal: a vector
```

1cms

Parts of 3 proteomic LC-MS samples

Description

The 1cms data consists of a 100 x 2000 x 3 array 1cms, a vector time of length 2000 and a vector mz of length 100. The LC-MS data in the array are a subset (samples 1, 2 and 5) of a larger set measured on a tryptic digest of E. coli proteins (see source section). Separate objects mz and rt give the values for the first two axis.

Peak picking leads to the object ldms.pks (see example section).

Usage

```
data(lcms)
```

Source

Nijmegen Proteomics Facility, Department of Laboratory Medicine, Radboud University Nijmegen Medical Centre. Data available (in different formats) at http://www.cac.science.ru.nl/research/data/ecoli/

References

Bloemberg, T.G., et al. (2010) "Improved parametric time warping for Proteomics", Chemometrics and Intelligent Laboratory Systems, **104** (1), 65 – 74.

```
## the lcms.pks object is generated in the following way:
## Not run:
data(lcms)
pick.peaks <- function(x, span) {
    span.width <- span * 2 + 1
    loc.max <- span.width + 1 -
        apply(embed(x, span.width), 1, which.max)
    loc.max[loc.max == 1 | loc.max == span.width] <- NA

pks <- loc.max + 0:(length(loc.max)-1)
    pks <- pks[!is.na(pks)]
    pks.tab <- table(pks)

pks.id <- as.numeric(names(pks.tab)[pks.tab > span])
    cbind(rt = pks.id, I = x[pks.id])
}
```

12 mzchannel2pktab

mzchannel2pktab

Conversion between peak lists from hyphenated MS (LCMS, GCMS, ...) data and input for stptw.

Description

Function pktab2mzchannel allows to split a list of peaks into several sublists, for instance on the basis of m/z values. The result can be aligned with stptw. The peak list can be obtained from packages like XCMS. The reverse function, mzchannel2pktab, simply gathers all peak positions in one matrix.

Usage

```
pktab2mzchannel(pktab, Ivalue = "maxo", masses = NULL, nMasses = 0, massDigits = 2)
mzchannel2pktab(mzchannels)
```

Arguments

pktab	a peak table as generated for example by XCMS. Necessary information: m/z value (column name "mz"), retention time (column name "rt") and intensity.
Ivalue	the name of the intensity value to be used. Default is "maxo", one of the columns generated by the XCMS package.
masses	a vector of specific masses
nMasses	an optional number limiting the number of mass channels. When both masses and nMasses are defined, the former takes preference
massDigits	number of significant mass digits - if no masses are supplied this number determines the number of distinct categories in the output
mzchannels	a list of peak matrices, e.g. the output of pktab2mzchannel

padzeros 13

Value

Function pktab2mzchannel returns a list of peak matrices; list elements have the name of the mz value that they represent. Function mzchannel2pktab returns one peak matrix where all masses are in a specific column.

Author(s)

Ron Wehrens

Examples

```
data(lcms)
## first couple of peaks in the first three channels
(smallset <- lapply(lcms.pks[[1]][1:3], head))
## all in one data matrix
allpeaks <- mzchannel2pktab(smallset)
## and back again
pktab2mzchannel(allpeaks, Ivalue = "I")</pre>
```

padzeros

Pad matrix with zeros

Description

Adds zeros to the left side of a matrix or vector, to its right side, or to both sides.

Usage

```
padzeros(data, nzeros, side="both")
```

Arguments

data the original matrix or vector

nzeros number of columns to add on one side

side to which side to add the zeros - choose between "both", "left" or "right"

Details

When data is a numeric vector, it is converted to a matrix of a single row.

Value

A matrix with the same number of rows as the original matrix, and extra columns containing zeros on the specified side or sides

Author(s)

Jan Gerretzen

14 plot.ptw

References

Bloemberg, T.G., et al. (2010) "Improved parametric time warping for Proteomics", Chemometrics and Intelligent Laboratory Systems, **104** (1), 65 – 74.

Examples

```
data(lcms)
lcms.z1 <- padzeros(lcms[75,,1], 250, side="left")
lcms.z2 <- padzeros(lcms[75,,1], 250, side="right")
lcms.z3 <- padzeros(lcms[75,,1], 250, side="both")
zeros <- rep(0, 250)

layout(matrix(1:4,2,2, byrow=TRUE))
plot(lcms[75,,1], type="1", main="Original signal")

plot(as.vector(lcms.z1), type="1", main="Padzeros left side")
points(1:250, zeros, col=2, lwd=0.08)

plot(as.vector(lcms.z2), type="1", main="Padzeros right side")
points(2001:2250, zeros, col=2, lwd=0.08)

plot(as.vector(lcms.z3), type="1", main="Padzeros both sides")
points(1:250, zeros, col=2, lwd=0.08)

points(2251:2500, zeros, col=2, lwd=0.08)</pre>
```

plot.ptw

Plot a ptw object

Description

The function plots a ptw object. It shows either the original and warped signals, or the warping function.

Usage

Arguments

X	object of class 'ptw'
what	"signal" plots the reference, sample and warped sample signal(s); "function" plots the warping function as warped 'time' - 'time' for the forward warping mode and as 'time' - warped 'time' for the backward warping mode.
type	"simultaneous" plots all signals or warping functions in one plot; "individual" generates multiple plots
ask	logical, whether to ask before showing a new plot
	further arguments to the plotting functions

predict.ptw 15

Author(s)

Jan Gerretzen, Ron Wehrens, Tom Bloemberg

Examples

predict.ptw

Prediction of warped signals

Description

Given a ptw object, predict either the signal at a certain warped time, or the warped time itself.

Usage

```
## S3 method for class 'ptw'
predict(object, newdata, what = c("response", "time"),
   RTref = NULL, ...)
```

Arguments

object	An object of class "ptw"
newdata	Optional vector or matrix of new data points. If what equals "response", the new data should be a vector or matrix of intensities. If what equals "time", the new data is a vector of time points (a matrix of time points makes no sense).
what	Either "response", in which case the function returns the warped signal, or "time", and then the function returns the warped time axis. That is, the time point in the warped sample corresponding to the given time point in the original sample.
RTref	Optional vector of retention times in the reference.

Further arguments, at the moment not used.

Value

The function returns a matrix (possibly containing only one row) of either warped time points or signals, warped according to the warping function defined in object. When warping signals individually, predict.ptw will check the dimension of newdata: if this is a vector or a matrix of one row, every single warping function will be applied to the one row. If the number of rows equals the number of warping functions, each row will be warped with its corresponding function. If the number of rows does not match the number of warping functions and is not equal to one, an error is given.

## result: good alignment with ref, differences between three profiles persist
```

ptw

Parametric Time Warping

Description

The main functions of the ptw package, performing parametric time warping of one or more samples. Features in the samples are optimally aligned with features in the reference(s). One may align a single sample to a single reference, several samples to a single reference, and several samples to several references. In the latter case, the number of references and samples should be equal. One may require that all samples are warped with the same warping function, or one may allow individual warpings for all samples.

Usage

```
ptw(ref, samp, selected.traces,
    init.coef = c(0, 1, 0), try = FALSE,
    warp.type = c("individual", "global"),
    optim.crit = c("WCC", "RMS"),
    mode = c("forward", "backward"),
    smooth.param = ifelse(try, 0, 1e05),
    trwdth = 20, trwdth.res = trwdth,
    verbose = FALSE, ...)
stptw(ref, samp, init.coef = c(0, 1, 0),
      trwdth = 20, trwdth.res = trwdth,
      nGlobal = ifelse(length(init.coef) > 3, 5, 0),
      ...)
## S3 method for class 'ptw'
summary(object, ...)
## S3 method for class 'ptw'
print(x, ...)
```

Arguments

ref

reference. Either a vector (containing one reference signal) or a matrix (one reference per row). If more than one reference is specified, the number of reference signals must equal the number of sample signals.

sample. A vector (containing one sample signal) or a matrix (one sample per row).

selected.traces

optional vector containing the row numbers to use from ref (if more than one reference signal is specified) and samp.

init.coef starting coefficients. The first number is the zeroth-order coefficient (i.e., a con-

stant shift); further numbers indicate linear, quadratic, ... stretches. The default is to start from the identity warping using a quadratic function (c(0, 1, 0))

try if try = TRUE, ptw does not optimize the warping but returns a ptw object con-

taining the warping for init.coef. Default: FALSE

warp. type default is to treat samples and references as single entities and align them indi-

vidually and independently. Using the argument warp.type = "global" leads to one alignment function; the samples are warped simultaneously to the refer-

ence(s). Also see details

optim.crit either "WCC" or "RMS". In both cases, the optimal value of the alignment leads

to a value of 0. For "WCC", this means that 1 - WCC is optimized rather than WCC

(where the optimal value equals 1)

mode either "forward" or "backward": the latter was the original implementation, ba-

sically for a point i in the original signal predicting the point j in the signal that would be in position i in the warped signal. The interpretation of the coefficients is counterintuitive. Therefore the default is "forward", simply predicting the location (time) in the warped signal of a particular point. Apart from possible numerical optimisation issues, both warpings should give the same net result.

smooth.param smoothing parameter for smoothing the reference and sample when optim.crit

equals "RMS". If no smoothing is required, set this to 0. The default is to use

smoothing in the optimization mode, and no smoothing otherwise

trwdth the width of the triangle in the WCC criterion during the optimization, given as

a number of data points. Default: 20

trwdth.res the width of the triangle in the WCC calculation in the calculation of the quality

of the final result. Default: equal to trwdth

verbose logical, default is FALSE. Whether to give output during the optimisation, which

may be useful for large data sets

. . . further arguments to optim

nGlobal for stick optimisations with more than three coefficients, a more powerful opti-

misation method is used (nloptr: in such cases nGlobal indicates the number

of times this method is employed.

x, object an object of class "ptw"

Details

Function ptw and friends is meant for profile data, where intensities have been recorded at regular time points; function stptw is meant for lists of peaks, for instance obtained after peak-picking the profile data. The latter option is less flexible (Euclidean distance and backward warping have not been implemented, and only global alignment is possible) but is much faster, especially for larger data sets.

In the optimization mode (try = FALSE), the function optimizes the warping coefficients using the chosen criterion (either "WCC" or "RMS"). For "RMS", the data are smoothed before the optimization, but the quality of the final warping is measured on the unsmoothed data. For "WCC", the warping is performed using trwdth as the triangle width, but the quality of the final solution is measured using trwdth.res.

If try = TRUE is used as an argument, the function does not start an optimization, but just calculates the warping for the given warp function (init.coef); if smooth.param is larger than zero for the RMS criterion, the RMS of the smoothed patterns is calculated. The WCC criterion uses trwidth.res as the triangle width in this case.

Five situations can be distinguished:

- 1. One sample and one reference: this obviously leads to one warping function regardless of the setting of warp. type.
- 2. Several samples, all warped to the same single reference, each with its own warping function: this is the default behaviour (warp.type = "individual")
- 3. Several samples, warped to an equal number of references (pair-wise), with their own warping functions: this is the default behaviour (warp.type = "individual")
- 4. Several samples, warped to one reference, with one warping function (warp.type = "global")
- 5. Several samples, warped to an equal number of references (pair-wise), with one warping function (warp.type = "global")

Value

A list of class "ptw" containing:

reference the reference(s) used as input sample the sample(s) used as input

warped.sample the warped sample
warp.coef the warping coefficients

warp. fun the warped indices (not for stptw)

crit.value the value of the chosen criterion, either "WCC" or "RMS"

optim.crit the chosen criterion, either "WCC" or "RMS"

warp. type the chosen type of warping, either "individual" or "global"

ptwgrid

Calculate RMS or WCC values on a grid

Description

Calculates values of the chosen optimization criterion (RMS or WCC) on a grid defined by the coefficients of the warping function.

Usage

```
ptwgrid(ref, samp, selected.traces,
  coef.mins, coef.maxs, coef.lengths,
  optim.crit = c("WCC", "RMS"),
  smooth.param = 1e05,
  trwdth = 20)
```

Arguments

ref	reference. Either a vector (containing one reference signal) or a matrix (one reference per row). If more than one reference is specified, the number of reference signals must equal the number of sample signals
samp	sample. A vector (containing one sample signal) or a matrix (one sample per row). If more than one sample is specified, the number of sample signals must equal the number of reference signals
selected.traces	3
	optional vector containing the row numbers to use from ref (if more than one reference signal is specified) and samp $$
coef.mins	a vector containing the respective minimal values of coefficients for the grid. The first number is the minimal zeroth-order coefficient (i.e., a constant shift); further numbers indicate the minimal linear, quadratic, stretches
coef.maxs	a vector containing the maximal values of coefficients for the grid
coef.lengths	a vector of the same length as coef.maxs and coef.mins containing the number of steps in which to vary the respective coefficients between their minimum and maximum value
optim.crit	either "WCC" or "RMS". In both cases, the optimal value of the alignment leads to a value of 0. For "WCC", this means that 1 – WCC is optimized rather than WCC (where the optimal value equals 1)
smooth.param	smoothing parameter for smoothing the reference and sample when optim.crit equals "RMS". If no smoothing is required, set this to 0

trwdth

the width of the triangle in the WCC criterion during the optimization, given as a number of data points. Default: 20

RMS 23

Details

In contrast to ptw, only the three situations leading to one warping function are distinguished here:

- 1. One sample and one reference;
- 2. Several samples, warped to an equal number of references (pair-wise);
- 3. Several samples, warped to a single reference.

Which situation is applicable is determined from the dimensions of ref and samp.

Value

An array of dimension length(coef.mins) and maximal indices per dimension specified by coef.lengths

Examples

RMS

Quality criteria for comparing patterns with shifts

Description

Functions to compare patterns with shifted features. These functions compare warped sample patterns to one or more reference patterns. RMS returns the usual root-mean-squared difference measure; WCC returns 1-wcc, where wcc indicates the weighted cross-correlation. Perfect alignment leads to a value of 0 for both criteria.

Internal function, not meant to be called directly by the user. In particular, note that the identity warping may lead to slightly different estimates than a direct comparison of the reference and sample signals - a warping even slightly outside the original range of 1 : ncol(ref) leads to NA values.

24 RMS

Usage

```
RMS(warp.coef, ref, samp, B, mode)
WCC(warp.coef, ref, samp, B, trwdth = 20, wghts, mode, ref.acors = NULL)
```

Arguments

warp.coef a vector of warping coefficients

ref reference signal; a matrix with one or more rows. If the number of rows is

greater than one, it should equal the number of rows in samp

sample signal; a matrix with one or more rows

B basis for warping function

mode either "forward" (new implementation, also used for warping peak lists) or "back-

ward" (classical implementation).

triangle width for the WCC function, expressed in the number of data points

wghts optional weights vector, will be calculated from triangle width if necessary.

Sometimes it is more efficient to pre-calculate it and give it as an argument

ref.acors autocorrelation of the reference. Since the reference is often unchanged over

multiple evaluations (e.g., during an optimization), it is useful to pre-calculate

this number

Details

All patterns in samp are warped using the same warping function, and then compared to ref, either pair-wise (when ref and samp are of the same size), or with the one pattern in ref.

Value

One number - either the WCC or RMS value

select.traces 25

select.traces	Select traces from a data set according to several criteria	

Description

For alignment purposes, it may be useful to select traces which show clear features, and to throw away traces that contain mainly noise. This function implements three ways to achieve this: CODA, a criterion similar to varimax, and a criterion based on the highest intensity.

Usage

Arguments

X a data matrix or an array. The first dimension signifies the traces from which a

selection is to be made. If X is a matrix, the first usually corresponds to samples and the second dimension is the spectral dimension. If X is an array, the data are assumed to come from a hyphenated experiment, with the first dimension the chromatographic dimension, the second the spectral dimension and the third

dimension corresponding to samples

criterion either Windig's CODA algorithm, a criterion calculating the variances of the

length-scaled spectra, or a criterion giving the height of the highest peak

window, smoothing

arguments to the coda function.

Details

The CODA criterion in essence selects traces with no baseline and no spikes, but still containing significant intensities. The variance criterion aims at something similar: it calculates the variance (or standard deviation) of every trace after length scaling - traces with a high value show few highly structured features, whereas traces with a low value show noise or a significant baseline. The intensity criterion simply returns the intensity of the highest peak. The latter two criteria are simpler than CODA but implicitly assume that the traces have been preprocessed (i.c., spikes have been removed).

Value

The function returns a list with components

crit.val a vector containing the values of the criterion for all traces. If X is an array, the

function is recursively applied to all samples (elements of the third dimension)

- the results are multiplied to obtain one criterion value per trace

trace.nrs the order of the traces (from large to small)

ntrace <- dim(lcms)[1]
lcms.selection <- select.traces(lcms[,,1:2], criterion = "var")
good <- lcms.selection$trace.nrs[1]
bad <- lcms.selection$trace.nrs[ntrace]

par(mfrow = c(1,2))
matplot(lcms[good,,1:2], type = 'l', lty = 1)
matplot(lcms[bad,,1:2], type = 'l', lty = 1)</pre>
```

warp.time

Transform time according to a given warping function

Description

Warp time points according to a warping function.

Usage

```
warp.time(tp, coef)
```

Arguments

tp A vector of time points, not necessarily equidistant.

coef The coefficients of the parametric time warping function: the first coefficient is

the constant shift, the second the linear stretch etcetera.

Value

The function returns a vector of warped time points.

## simple shift and compression
warp.time(time, c(-10, .99))</pre>
```

wcc

Weighted auto- and cross-correlation measures

Description

Functions to calculate weighted auto- and cross-correlation measures. The wcc is a suitable measure for the similarity of two patterns when features may be shifted. Identical patterns lead to a wcc value of 1.

Functions wcc and wac are meant for profile data (intensities measured at equidistant time points), whereas wcc.st and wac.st are meant for peak lists. In general, wcc values calculated for profiles will be higher since they will also include the large similarity in the empty spaces, i.e., parts of the profiles where no peaks are present (and that will appear to be perfectly aligned), whereas the peak-based version concentrates only on the peaks.

Usage

```
wcc(pattern1, pattern2, trwdth, wghts = NULL, acors1 = NULL, acors2 = NULL)
wac(pattern1, trwdth, wghts = NULL)
```

Arguments

pattern1, pattern2

input patterns, typically spectra. Vectors

trwdth triangle width, given in the number of data po

triangle width, given in the number of data points for the profile functions, and

in the actual retention times for the stick-based warpings.

wghts optional weights vector, will be calculated from triangle width if necessary.

Sometimes it is more efficient to pre-calculate it and give it as an argument

acors1, acors2 autocorrelations of the input patterns. If not provided, they are calculated

Details

Functions wcc and wac are defined such that the triangle width stands for the number of points on one side of **and including** the current point. Thus, a trwdth of 0 signifies a non-existent triangle and results in an error; a trwdth equal to 1 only includes the current point with weight 1 and no neighbouring points. For the stick-based equivalents, the units of the time axis are used for the triangle width.

Value

One number, the weighted autocorrelation or crosscorrelation
